

# UG434: Silicon Labs *Bluetooth*® C Application Developer's Guide for SDK v3.x

This document is an essential reference for everybody developing C-based applications for the Silicon Labs Wireless Gecko products using the Silicon Labs Bluetooth stack. The guide covers the Bluetooth stack architecture, application development flow, usage and limitations of the MCU core and peripherals, stack configuration options, and stack resource usage. This version applies to the Silicon Labs Bluetooth Software Development Kit (SDK) version 3.0.x and higher.

The purpose of the document is to capture and fill in the blanks between the Bluetooth Stack API reference, Gecko SDK API reference, and Wireless Gecko reference manuals, when developing Bluetooth applications for the Wireless Geckos. This document exposes details that will help developers make the most out of the available hardware resources.

## KEY POINTS

- Project structure and development flow
- Bluetooth stack and Wireless Gecko configuration
- Interrupt handling
- Event and sleep management
- Resource usage and available resources

## 1. Introduction

This document is a C developer's guide for the Silicon Labs Bluetooth stack.

The document covers various angles of development, and is an important reference to everyone developing in C for Wireless Gecko products that are running the Bluetooth stack.

The document covers the following topics:

- Section [2. Application Development Flow](#) discusses the application development flow.
- Section [3. Project Structure](#) reviews project structure.
- Section [4. Configuring the Bluetooth Stack and a Wireless Gecko Device](#) explains the project include libraries and the actual Wireless Gecko configuration in the application code.
- Section [5. Bluetooth Stack Event Handling](#) is an important piece for everyone developing with the Silicon Labs Bluetooth stack, as it explains how the application runs in sync with the stack in an event-based architecture.
- Section [6. Interrupts](#) and section [7. Wireless Gecko Resources](#) touch on the topics of peripherals and the chipset resources, covering what is reserved for the stack usage, how interrupts should be handled, and the stack's memory footprint and available memory for the application.

### 1.1 About this Version

The current version of Silicon Labs' Bluetooth SDK is 3.0.x.

Currently supported compilers and IDE versions are:

- **IDE:** Simplicity Studio 5.0.0 or newer
- **Compiler:** IAR v8.30.1 and GCC 7.2.1

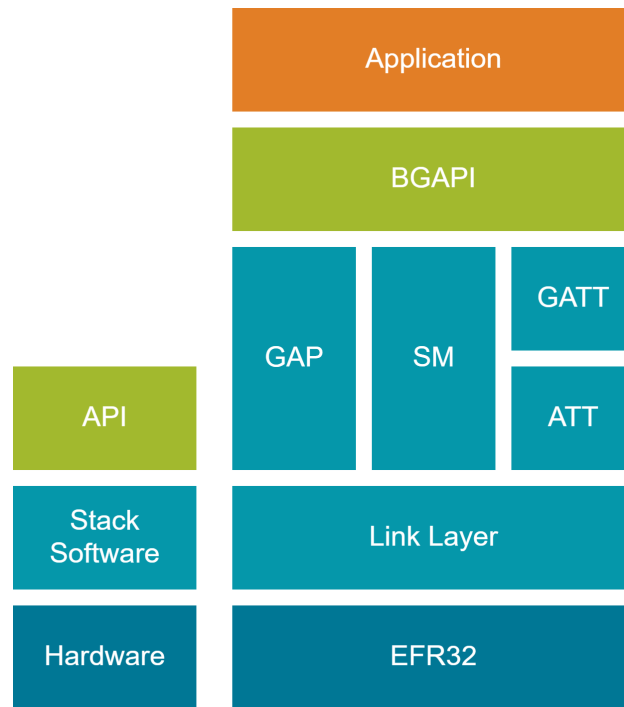

### 1.2 Prerequisites

This documents assumes the current version of Silicon Labs' Bluetooth SDK has been properly installed to the development machine (Windows, MAC OSX, or Linux), and that the reader is familiar with the quick start guides and with the SDK's examples. Also, the reader should have a basic understanding of Bluetooth technology. For more information, see *UG103.14: Bluetooth Technology Fundamentals*.

For instructions on getting started using example applications in Silicon Labs Simplicity Studio development environment, see *QSG169: Bluetooth® SDK v3.x Quick Start Guide*.

## 2. Application Development Flow

The following figure describes the high-level firmware structure. The developer creates an application on top of the stack, which Silicon Labs provides as a precompiled object-file, enabling the Bluetooth connectivity for the end-device.

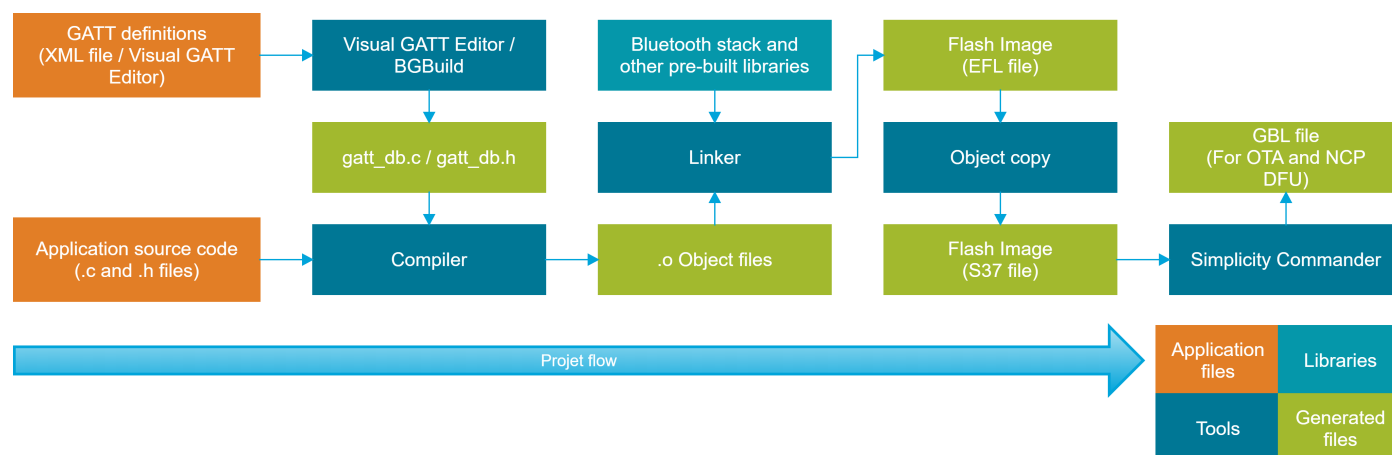

**Figure 2.1. Bluetooth Stack Architecture Block Diagram**

The Bluetooth stack contains following blocks.

- **Bootloader**—The Gecko Bootloader is not part of the stack but is provided with the Bluetooth SDK. See *UG266: Gecko Bootloader User Guide* and *AN1086: Using the Gecko Bootloader with Silicon Labs Bluetooth Applications* for more information. For information on bootloading in general, see *UG103.06: Bootloading Fundamentals*.
- **Bluetooth stack**—Bluetooth functionality consisting of link layer, generic access profile, security manager, attribute protocol, and generic attribute profile.
- **Bluetooth AppLoader**—An application that starts after the bootloader. It checks if the user application is valid and, if it is, AppLoader starts the application. If the application image is not valid, AppLoader starts the OTA process to try to receive a valid application image. This requires using the Gecko Bootloader.

## 2.1 Application Build Flow

**Figure 2.2. Bluetooth Project Build Flow**

Building a project starts by defining the Bluetooth services and characteristics (GATT definitions) and by writing the application source code from Silicon Labs-provided examples or an empty project template, as described in *QSG169: Bluetooth® SDK v3.x Quick Start Guide*.

SDK v2.1.0 and later offer two ways to define Bluetooth services and characteristics. The first option is the Visual GATT Editor GUI in Simplicity Studio. This is a graphical tool for designing the GATT and for generating *gatt\_db.c* and *gatt\_db.h*. Additionally it can import *.xml* and *.bgproj* GATT definition files. The Visual GATT Editor is the default tool for GATT definition and generation in Simplicity Studio projects.

The second option is to create an *.xml* or *.bgproj* according to the *UG118: Blue Gecko Bluetooth® Profile Toolkit Developer's Guide* and then use the BGBuild executable as a pre-compilation step to convert the GATT definition file into *.c* and *.h*. This method is used in IAR Embedded Workbench projects.

Compiling the project generates an object file, which is then linked with the pre-compiled libraries provided in the SDK. The output of the linking is a flash image that can be programmed to the supported Wireless Gecko devices.

## 3. Project Structure

This section explains the application project structure and the mandatory and optional resources that must be included in the project.

### 3.1 Bluetooth Files

#### Library Files

The Bluetooth stack libraries are:

- **binapploader.o**: Binary image of the Bluetooth AppLoader, provides the optional OTA (Over-the-Air) functionality.
- **binapploader\_nvm3.o**: Binary image of the Bluetooth AppLoader for Series 1 with NVM3 support.
- **libbluetooth.a**: Bluetooth stack library.
- **libpsstore.a**: PS Store functionality for the Bluetooth stack. This is not available on EFR32[B|M]G2x devices. NVM3 must be used instead.

#### RAIL

The Bluetooth stack uses RAIL to access the radio and RAIL libraries needs to be linked with Bluetooth stack. RAIL has separate libraries for each device family and for single- and multi-protocol environments. RAIL libraries are provided in the Gecko SDK Suite. For more information refer to *UG103.13: RAIL Fundamentals* and other RAIL documentation.

**Note:** To ensure regulatory compliance of the radio module, the Bluetooth stack for the radio module needs to be linked together with the RAIL library and the configuration library for the radio module. These are `librail_module_<soc family><compiler>_release.a` and `lib-rail_config<modulename>.a`.

#### EMLIB and EMDRV

The Bluetooth stack uses EMLIB and EMDRV libraries to access EFR32 hardware. EMLIB and EMDRV peripheral libraries are provided in source code and they must be included in the project. EMLIB and EMDRV are part of the Gecko SDK Suite. For more details on EMLIB and EMDRV, see platform EMDRV documentation and EMLIB documentation on <https://docs.silabs.com/>.

#### mbed TLS

The Bluetooth stack uses the Mbedtls library for cryptographic operations. The Mbedtls library is provided in source code and must be included in the project. Mbedtls is part of the Gecko SDK Suite. For more details, refer to the [Mbedtls documentation](#).

#### Sleep Timer

Sleep Timer is a platform component providing for software timers, timekeeping and date functionality. The Bluetooth stack uses it for deep sleep and it must be included in the project. See [platform sleeptimer documentation](#).

#### Power Manager

Power Manager is a platform component that manages the system's energy modes. Its main purpose is to transition the system to a low energy mode when the processor has nothing to execute. See the reference for your MCU on <https://docs.silabs.com/> under Modules>Platform Services>Power Manager.

#### Header Files

##### sl\_bt\_version.h

This file contains the Bluetooth stack version.

## API Header Files

These files define the Bluetooth stack API.

These files serve two purposes: first they contain the actual Bluetooth stack API and the commands and events for the stack, and second they provide a configuration and event management API to the Bluetooth stack.

The configuration, event, and sleep management API is described below.

```
sl_status_t sl_bt_init_stack(const sl_bt_configuration_t *config)
```

This function takes a single argument - a pointer to a `sl_bt_configuration_t` struct. Its purpose is to configure and initialize the Bluetooth stack with the parameters provided in the struct. Once the function `sl_bt_init_stack()` is called, each required stack component must be initialized separately. This separation allows memory optimization, by not including those stack components that are not needed. Project Configurator in Simplicity Studio 5 (SSv5) will take care of the stack initialization. In non-SSv5 applications the application must call `sl_bt_init_stack()` and then initialize BGAPI classes.

The following APIs can be used to initialize stack components separately:

- `sl_bt_class_dfu_init();`
- `sl_bt_class_system_init();`
- `sl_bt_class_gap_init();`
- `sl_bt_class_avertiser_init();`
- `sl_bt_class_scanner_init();`
- `sl_bt_class_sync_init();`
- `sl_bt_class_connection_init();`
- `sl_bt_class_gatt_init();`
- `sl_bt_class_gatt_server_init();`
- `sl_bt_class_ota_init();`
- `sl_bt_class_nvm_init();`
- `sl_bt_class_test_init();`
- `sl_bt_class_sm_init();`
- `sl_bt_class_coex_init();`
- `sl_bt_class_cte_transmitter_init();`
- `sl_bt_class_cte_receiver_init();`

```
sl_status_t sl_bt_wait_event(sl_bt_msg_t* evt)
```

This is a blocking function that waits for events coming from the Bluetooth stack and blocks until an event is received. Once an event has been received, an event object is copied into the memory provided by application.

The Bluetooth stack requests EM2 power mode automatically from the power manager if LF clock accuracy meets the 500 ppm requirement. Otherwise, only EM1 is allowed. The device will automatically enter EM1 or EM2 mode when no events are being received from the Bluetooth stack. Using `sl_bt_wait_event()` is the easiest way to make sure the device is in the lowest power sleep mode whenever possible.

The Bluetooth stack's event handling is discussed in detail in section [5. Bluetooth Stack Event Handling](#).

```
sl_status_t sl_bt_pop_event(sl_bt_msg_t* evt)
```

This is a non-blocking function to request Bluetooth events from the Bluetooth stack. When an event is requested and the event queue is not empty, an event object is copied into the memory provided by application. If there are no events in the event queue, `SL_STATUS_NOT_FOUND` is returned.

When using this non-blocking event listener, the EM sleep modes have to be managed by the application code as they are not managed automatically by the Bluetooth stack. The sleep mode management is done with `power manager`.

The stack's event handling is discussed in detail in section [5. Bluetooth Stack Event Handling](#).

```
int sl_bt_event_pending(void)
```

This function checks to see if any Bluetooth stack events are pending in the event queue. If a pending Bluetooth event is found, the function returns a non-zero value to indicate that the event should be processed by either `sl_bt_pop_event()` or `sl_bt_wait_event()`. If no event is found, zero is returned.

**sl\_bt\_types.h**

**sl\_bt\_stack\_init.h**

**sl\_bt\_api.h**

These files contains the Bluetooth stack API and the commands and events for the stack, and a configuration API for the Bluetooth stack.

**sl\_bt\_ncp\_host\_api.c, sl\_bt\_ncp\_host.c, sl\_bt\_ncp\_host.h and sl\_bt\_internal.h**

These files are used when developing applications for an external host. They provide the API definitions and adaptation layer between the host application and the BGAPI serial protocol.

### 3.2 GATT Database

The GATT (Generic Attribute Profile) database is a standardized way of describing the Bluetooth profiles, services, and characteristics of a Bluetooth device. With the Silicon Labs Bluetooth stack, the GATT definitions are either directly edited in the Visual GATT Editor GUI in Simplicity Studio or are written in XML and passed to the BGBuild executable as a pre-build task. For more information on how to create GATT databases and the syntax, refer to *UG118: Blue Gecko Bluetooth® Smart Profile Toolkit Developer's Guide*.

**gatt\_db.c and gatt\_db.h**

The `gatt_db.c` defines the GATT database structure and content, and is auto-generated by BGBuild or by the Visual GATT Editor. `gatt_db.h` includes this database and the handles of local characteristics and services. Type definitions of GATT are automatically included from `bg_gatt_db_def.h` to `gatt_db.h`.

### 3.3 Device Firmware Upgrade

Device Firmware Upgrade (DFU) is the process of upgrading the application either over a serial link or over-the-air (OTA). In both cases the application needs to add the following file to enable the support for DFU.

**application\_properties.c**

This file includes the application properties struct that contains information about the application image, such as type, version, and security. The struct is defined in `application_properties.h` in the Gecko Bootloader API. A pre-generated file is included in Simplicity Studio projects, which can be modified to include application-specific properties. The application properties can be accessed using the Gecko Bootloader API. The following members can be updated by changing the defines:

```
// Version number for this application (uint32_t)
#define APP_PROPERTIES_VERSION

// Unique ID (e.g. UUID or GUID) for the product this application is built for (uint8_t[16])
#define APP_PROPERTIES_ID
```

When using the OTA process with Bluetooth AppLoader, a pointer to the application properties struct needs to be set to application vector table vector 13. This is enabled automatically when using the default startup file and the struct name is `sl_app_properties`.

### 3.4 RTOS Support

The Bluetooth stack can also run on Micrium RTOS. In this case the following files are added to the project: *sl\_bt\_rtos\_adaptation.c* and *sl\_bt\_rtos\_adaptation.h*.

#### **sl\_bt\_rtos\_adaptation.c and sl\_bt\_rtos\_adaptation.h**

*sl\_bt\_rtos\_adaptation.c* and *sl\_bt\_rtos\_adaptation.h* provide the Micrium OS tasks for the IPC (Inter-Process Communication) with the Bluetooth stack and other Micrium OS tasks.

Support for RTOS needs to be configured for the Bluetooth Stack in the *sl\_bt\_configuration\_t* struct. The *config\_flags* field needs to have *SL\_BT\_CONFIG\_FLAG\_RTOS* set. This causes the Bluetooth stack to rely on the Micrium OS for sleeping, rather than sleeping directly. *scheduler\_callback* and *stack\_schedule\_callback* must be configured to call proper functions. These callbacks are used to wake up the corresponding tasks.

The Bluetooth Stack configuration to use with Micrium OS is as follows:

```
.config_flags = SL_BT_CONFIG_FLAG_RTOS,  
.scheduler_callback = sli_bt_rtos_ll_callback,  
.stack_schedule_callback = sli_bt_rtos_stack_callback,
```

*sl\_bt\_rtos\_init()* can be called to initialize the stack and create needed RTOS tasks.

```
void sl_bt_rtos_init();
```

It calls function *sl\_bt\_init()* to initialize the Bluetooth stack.

### 3.5 Multiprotocol Support

When the Bluetooth Stack is used in a multiprotocol environment, multiprotocol features in the Bluetooth stack must be enabled with following function:

```
sl_bt__init_multiprotocol();
```

Using Bluetooth in a multiprotocol environment also requires using the RAIL library with multiprotocol support.

### 3.6 Platform Components

The v3.x Bluetooth stack relies on many platform components that are part of the underlying Gecko Platform infrastructure of the Gecko SDK Suite. The *autogen* folder contains sources for initializing the hardware and processing events. The *config* folder includes hardware and stack configuration options.

## 4. Configuring the Bluetooth Stack and a Wireless Gecko Device

To run the Bluetooth stack and an application on a Wireless Gecko, the MCU and its peripherals have to be properly configured.

### 4.1 Wireless Gecko MCU and Peripherals Configuration

#### **sl\_system\_init()**

The `sl_system_init()` function is used to initialize the system. It will call platform, driver, service, stack and internal app init functions, which are located in the `autogen` folder.

#### **App\_init()**

The `App_init()` function is used to initialize application-specific features.

#### 4.1.1 Adaptive Frequency Hopping

Bluetooth Stack implements Adaptive Frequency Hopping (AFH), conforming with the ETSI EN 300 328 standard. AFH is required when using transmit power +10 dBm and over. AFH may also provide performance improvement by avoiding congested channels.

To enable AFH in the Bluetooth stack, the following initialization function must be called:

```
void sl_bt_init_afh();
```

This is included automatically when including the `bluetooth_feature_afh` component. In a master-slave connection, both ends can use AFH independent of each other. The master may be non-adaptive, but the slave still may need to be adaptive. The standard allows using control transfer on a blocked channel. For compliance reasons if the slave detects that a blocked channel is in use it will only send a single packet on that channel to prevent connection timeouts.

**Note:** Legacy advertising does NOT use Adaptive Frequency Hopping. Legacy advertising uses 3 channels, and AFH needs a minimum of 15 channels to fulfill the requirements of the ETSI standard. Extended advertising must be used to enable AFH with advertising.

### 4.1.2 Bluetooth Clocks

The clock settings are initialized in the `sl_platform_init()` function in `sl_event_handler.c`. Clock settings include initializations of oscillators (HFXO, LFXO, and LFRCO) with parameters such as tuning, initialization of the clocks (HFCLK, LFCLK, LFA, LFB, LFE), and the assignment of clocks to oscillators. Note: The peripheral clocks (like GPIO clock, TIMER clock) are not enabled in this function. They must be enabled when initializing a peripheral.

#### HFCLK

HFCLK is used for a radio protocol timer (PROTIMER). HFCLK is a high frequency clock where accuracy must be at least  $\pm 50$  ppm. This clock needs an external crystal to be sufficiently accurate (HFXO).

The HFXO initialization configures the external crystals for timing-critical connection and sleep management. An HFXO has to be set as the high frequency clock (HFCLK) and physically connected to a Wireless Gecko's HFXO input pins.

#### LFCLK

LFCLK, the low frequency clock, is used for two purposes. In the Bluetooth stack it is used for Bluetooth protocol timing. It is also needed to keep track of time during sleep mode.

When a device enters into sleep mode, the current state of PROTIMER is saved. When the device wakes up it calculates how many ticks of sleep clock has passed and adjusts the PROTIMER accordingly. To the radio it appears that PROTIMER has been constantly ticking.

The accuracy of this clock depends on the operating mode of the device. When advertising or scanning, accuracy is not that important, but when a connection is open the accuracy must be at least  $\pm 500$  ppm. This clock can be driven either by LFXO, PLFRCO (EFR32[B]M]G13 or [B]M]GM13), or LFRCO (EFR32[B]M]G2x or [B]M]GM2x), depending on the accuracy requirements. If applications only require advertising or scanning, LFRCO can be used as the clock source. However, if Bluetooth connections are required, the clock source must be either LFXO, PLFRCO (EFR32[B]M]G13 or [B]M]GM13) or LFRCO with High Precision Mode (EFR32[B]M]G22 or [B]M]GM22). When using PLFRCO or LFRCO, the accuracy of the clock must be configured to  $\pm 500$  ppm.

In the default configuration, LFXO is connected to the Wireless Gecko and set as the clock source for LFCLK. If the design only has PLFRCO or LFRCO with High Precision Mode, PLFRCO or LFRCO is connected and set as the clock source.

If none of LFXO, PLFRCO or LFRCO with High Precision Mode is connected in the design, sleeping is disabled automatically if LF clock accuracy does not meet the 500 ppm requirement.

#### HFRCODPLL

HFRCODPLL is a high frequency clock that is used as a system clock with the Bluetooth stack in Series 2 devices. On EFR32[B]M]G21x HFRCODPLL needs to be configured to 80 MHz and set as the system clock source.

```
CMU_HFRCODPLLBandSet(cmuHFRCODPLLFreq_80MHz);  
CMU_ClockSelectSet(cmuClock_SYSClk, cmuSelect_HFRCODPLL);
```

## CTUNE

The examples have the crystal tune (CTUNE) settings for both HFXO and LFXO set by default to work with all of the Silicon Labs' Bluetooth modules, reference designs, and radio boards. However, in some cases the end-product design requires specific crystal calibration, either per device or per design. The CTUNE value can be adjusted according to the design in the `sl_device_init_hfxo()` function.

For more information on configuring the HFXO and LFXO, refer to the EFR32 Reference Manual.

### Default HFXO CTUNE Value

The system checks multiple sources for the default HFXO CTUNE value, using the following logical order:

1. CTUNE PSKEY is set. This key has ID 50 (32 in hex) and contains 2 bytes of data for the 16 bit CTUNE value. This can be programmed with the BGAPI command `sl_bt_nvm_save`.
2. Calibration value exists in DEVINFO. Some modules contain a factory-programmed value in the DEVINFO-page.
3. Manufacturing token exists in the user data page. This is programmed by the developer, or it can be automatically set by Simplicity Studio if the board EEPROM contains the value. This token consists of 2 bytes, located at offset 0x0100 from the starting address of the User Data page. Refer to the EFR32 Reference Manual for your specific EFR variant for the full flash mapping.
4. If a radio board is selected when generating the project, then use default value from board header file
5. If nothing else is found, use the default value from CMU header file.

**Note:** The Bluetooth stack only supports 38.4 MHz HFXO frequency; no other HFXO frequencies are supported.

### 4.1.3 DC-DC Configuration

On devices that have DC-DC, the configuration is set in the `sl_device_init_dcdc()` function in `sl_event_handler.c`. The examples in the SDK have DC-DC configuration set to work with the Silicon Labs' Bluetooth modules, radio boards, and reference designs, but custom designs might require specific DC-DC settings. These custom settings can be set in `sl_device_init_dcdc_xx.c`.

```
/** DCDC regulator initialization structure. */
typedef struct {
    EMU_DcdcMode_TypeDef      mode;           /**< DCDC mode. */
    EMU_VreginCmpThreshold_TypeDef cmpThreshold; /**< VREGIN comparator threshold. */
    EMU_DcdcTonMaxTimeout_TypeDef tonMax;      /**< Ton max timeout control. */
    bool                      dcmOnlyEn;      /**< DCM only mode enable. */
    EMU_DcdcDriveSpeed_TypeDef driveSpeedEM01; /**< DCDC drive speed in EM0/1. */
    EMU_DcdcDriveSpeed_TypeDef driveSpeedEM23; /**< DCDC drive speed in EM2/3. */
    EMU_DcdcPeakCurrent_TypeDef peakCurrentEM01; /**< EM0/1 peak current setting. */
    EMU_DcdcPeakCurrent_TypeDef peakCurrentEM23; /**< EM2/3 peak current setting. */
} EMU_DCDCInit_TypeDef;
```

For more information on configuring the DC-DC, refer to the EFR32 Reference Manual, Chapter 11, and *AN0948: Power Configurations and DC-DC*.

### 4.1.4 LNA

A low-noise amplifier (LNA) is an electronic amplifier that amplifies a very low-power signal without significantly degrading its signal-to-noise ratio. The LNA improves RF sensitivity.

An LNA is provided on-board in some MGM12P modules as part of front-end module (FEM). To use LNA in these modules, the FEM needs to be correctly configured and enabled. The FEM is configured in `sl_fem_util_config.h`.

FEM is initialized in `sl_fem_util_init()` within the `sl_service_init()` function if the board supports FEM.

### 4.1.5 Periodic Advertising

Periodic advertising enables multiple listeners to be synchronized with a single advertising device. Thus it is a form of multicast.

Each listener needs to be synchronized to the advertising device before they start receiving data. Periodic advertising uses a scanner on the listening device to establish a synchronization to the advertising device. After synchronization the scanner can then be stopped. This makes it much more power-efficient than using the scanner full time for listening for broadcast advertisements.

The periodic advertising consists of two components: periodic advertiser role and periodic advertising synchronization on listening side. These two components are independent of each other and need to be initialized separately.

#### Periodic Advertiser

`max_advertisers` in the Bluetooth configuration also configures the maximum number of periodic advertisers.

To enable Periodic Advertiser in the Bluetooth stack, the following initialization function must be called after the generic `sl_bt_init_stack()` function, which is added automatically by including the `bluetooth_feature_periodic_adv` component:

```
void sl_bt_init_periodic_advertising();
```

#### Periodic Advertising Synchronization

`max_periodic_sync` in the Bluetooth config is used to configure the maximum number of synchronizations the Bluetooth stack needs to support.

To enable Periodic Advertising Synchronization in the Bluetooth stack, the following initialization function must be called after the generic `sl_bt_init_stack()` function by including the `bluetooth_feature_sync` component:

```
void sl_bt_class_sync_init();
```

This command also initializes the BGAPI sync class, making it available to use.

### 4.1.6 PTI

PTI (Packet Trace Interface) is a built-in block in the Wireless Gecko SoCs to route incoming and outgoing radio packets as raw data to the debug interface. These packets can then be captured and displayed in Simplicity Studio's Network Analyzer. Network Analyzer has a decoder for Bluetooth packets and can be used to debug, analyze, and measure Bluetooth networks.

PTI is initialized in `sl_rail_util_pti_init()` within the `sl_stack_init()` function. The baudrate can be set using the `SL_RAIL_UTIL_PTI_BAUD_RATE_HZ` definition, and pins can be configured using the definitions with the `SL_RAIL_UTIL_PTI_DOUT_` and `SL_RAIL_UTIL_PTI_DFRAME_` prefix in `sl_rail_util_pti_config.h`.

### 4.1.7 Transmit Power

Transmit power of Bluetooth depends on the maximum power allowed by the radio, the software configuration, RF path gain compensation, and usage of Adaptive Frequency Hopping (AFH).

The ETSI EN 300 328 standard requires using AFH when transmitter power is +10 dBm and over.

The maximum allowed power is limited to less than +10 dBm if prevented by adaptivity requirements. The ETSI standard requires that at least 15 channels are in use for AFH. This requirement prevents using +10 dBm and over in the following cases: legacy advertising, scan responses, and in connections, when not enough channels are available.

### 4.1.8 Whitelisting

Whitelisting is used to filter devices. Currently it is only supported when discovering devices. Connection requests, scan requests from remote devices during advertising, and connection initiations are not restricted by the whitelist.

Whitelist size matches the configuration for the max number of bonded devices. If the max number of bonded devices is changed when using whitelisting, the device needs to be reset before the new setting takes effect.

Bonded devices are added to the whitelist automatically. Alternatively they can be added manually with the BGAPI command `sl_bt_sm_add_to_whitelist()`.

Random address resolving is not supported. Devices using resolvable random addresses will not be visible during scanning. Since most Android and iOS phones use resolvable random addresses, the whitelisting feature will effectively block these devices during device discovery.

To enable whitelisting in the Bluetooth stack, the following initialization function must be called after the generic `sl_bt_init_stack()` function:

```
void sl_bt_init_whitelisting();
```

This is included automatically when including the `bluetooth_feature_whitelisting` component. When the function is enabled, it can be enabled and disabled at runtime by the BGAPI command `sl_bt_gap_enable_whitelisting()`.

Connections may be restricted to only bonded or whitelisted devices separately using `sl_bt_sm_configure()`. This does not require enabling whitelisting.

### 4.1.9 Wi-Fi coexistence

Wi-Fi coexistence (COEX) is a protocol where Bluetooth and Wi-Fi arbitrate which protocol can use the radio for transmitting. When enabled, it improves the performance of Wi-Fi and Bluetooth. COEX is configured in `sl_bluetooth_coex_config.h`.

To enable COEX, call the following function after `sl_bt_init_stack()`.

```
sl_bt_init_coex_hal();
```

This is included automatically when including the `bluetooth_feature_coex` component. COEX implements the GPIO interface to the Wi-Fi IC. It depends on EMLIB `em_gpio.c` and EMDRV `gpiointerrupt.c` and requires both files to be included in the project.

### 4.1.10 OTA Configuration

Bluetooth Over-the-Air (OTA) firmware upgrades are supported, since part of the firmware upgrade is handled by the Bluetooth AppLoader application. Enable OTA configuration with the `bluetooth_feature_ota_config` component

The OTA mode can be configured using the `sl_bt_ota_set_configuration()` function, which can, for example, set OTA to use a static random address, instead of a public address. For other options refer to the BGAPI document.

When the Wireless Gecko is in AppLoader's OTA mode, its device name and the device name length can be configured with the `sl_bt_ota_set_device_name()` function. The advertisement data used in OTA mode can be set to use custom data instead of the default one with `sl_bt_ota_set_advertising_data()`.

If the device is not using the default RF path it can be configured for OTA mode with `sl_bt_ota_set_rf_path()`.

Finally, setting the device to OTA DFU mode should be secured so that only trusted devices have that capability.

For more details about OTA firmware updates, refer to *UG266: Silicon Labs Gecko Bootloader User's Guide* and *AN1086: Using the Gecko Bootloader with Silicon Labs Bluetooth Applications*.

#### 4.1.11 Even Connection Distribution Algorithm

The even connection distribution algorithm is designed to be used especially with applications that involve several concurrent connections. The algorithm tries to distribute the connections such a way that they are distributed over time as evenly as possible without overlapping, and all connections should get an equal share of the air interface resource.

For optimal performance the algorithm user should:

- Initiate the first connection with the longest connection interval if all connections do not have the same interval.
- Set the connection intervals of the other connections such that they are, or allow (via min-max range), integer fractions of the first interval.
- Make the first interval long enough such that all connections would fit within the interval with a reasonable transmission time.

The algorithm and the connections can be expected to work if the above recommendations are not followed, but performance is not likely be optimal.

By default the link layer uses the legacy Random Connection Distribution algorithm. The Even Connection Distribution algorithm can be enabled by including the component *bluetooth\_feature\_ll\_even\_scheduling* or calling link layer function `ll_connSchAlgorithmEvenEnable()` during the software initialization phase. As the even connection scheduling mechanism is meant to be used with multiple (up to 32) concurrent connections, the buffer and heap sizes are recommended to be increased as follows.

```
SL_BT_CONFIG_BUFFER_SIZE 20160
SL_HEAP_SIZE 22520
```

## 4.2 Bluetooth Configuration with `sl_bt_init_stack()`

The `sl_bt_init_stack()` function is used to configure the Bluetooth stack, including memory buffer size that is allocated for connections. None of the Bluetooth stack functions can be used before the Bluetooth stack has been configured.

Bluetooth stack configuration example:

```
#define SL_BT_CONFIG_DEFAULT
{
    .config_flags = SL_BT_CONFIG_FLAGS,
    .bluetooth.max_connections = SL_BT_CONFIG_MAX_CONNECTIONS,
    .bluetooth.max_advertisers = SL_BT_CONFIG_MAX_ADVERTISERS,
    .bluetooth.max_periodic_sync = SL_BT_CONFIG_MAX_PERIODIC_ADVERTISING_SYNC,
    .bluetooth.max_buffer_memory = SL_BT_CONFIG_BUFFER_SIZE,
    .scheduler_callback = SL_BT_CONFIG_LL_CALLBACK,
    .stack_schedule_callback = SL_BT_CONFIG_STACK_CALLBACK,
    .gattddb = &bg_gattddb_data,
    .max_timers = SL_BT_CONFIG_MAX_SOFTWARE_TIMERS,
    .rf.tx_gain = SL_BT_CONFIG_RF_PATH_GAIN_TX,
    .rf.rx_gain = SL_BT_CONFIG_RF_PATH_GAIN_RX,
}
```

Configuration options in the `sl_bt_init_stack()` function are: Bluetooth connection count, advertiser count, periodic advertisement sync count, memory buffer size, number of timers, GATT database, and PA configuration.

Once the function `sl_bt_init_stack()` is called, each stack component used has to be initialized separately. This separation allows memory optimization by not including unnecessary stack components.

The following APIs can be used to initialize stack components separately. The calls to the initialization functions are added automatically by including the respective component.

<code>sl_bt_class_advertiser_init()</code>	The commands and events in this class are related to advertising functionalities in GAP peripheral and broadcaster roles.
<code>sl_bt_class_coex_init()</code>	Coexistence interface is enabled and initialized with <code>sl_bt_init_coex_hal</code> function.
<code>sl_bt_class_connection_init()</code>	The commands and events in this class are related to managing connection establishment, parameter setting, and disconnection procedures.
<code>sl_bt_class_cte_receiver_init()</code>	Commands and events in this class manage Constant Tone Extension (CTE) receiving.
<code>sl_bt_class_cte_transmitter_init()</code>	Commands and events in this class manage Constant Tone Extension (CTE) transmission.
<code>sl_bt_class_dfu_init()</code>	These commands and events are related to controlling firmware updates over the configured host interface and are available only when the device is booted in DFU mode. Usually not needed in application.
<code>sl_bt_class_gap_init()</code>	The commands and events in this class are related to the Generic Access Profile (GAP) in Bluetooth.
<code>sl_bt_class_gatt_init()</code>	The commands and events in this class are used to browse and manage attributes in a remote GATT server.
<code>sl_bt_class_gatt_server_init()</code>	These commands and events are used by the local GATT server to manage the local GATT database.
<code>sl_bt_class_nvm_init()</code>	Manage user data in NVM keys in the flash memory of the Bluetooth device.
<code>sl_bt_class_ota_init()</code>	Commands for configuring OTA DFU.
<code>sl_bt_class_scanner_init()</code>	The commands and events in this class are related to scanning functionalities in GAP central and observer roles.

<code>sl_bt_class_sm_init()</code>	The commands in this class manage Bluetooth security, including commands for starting and stopping encryption and commands for management of all bonding operations.
<code>sl_bt_class_sync_init()</code>	Provides the periodic advertising synchronization feature.
<code>sl_bt_class_system_init()</code>	Commands and events in this class can be used to access and query the local device.
<code>sl_bt_class_test_init()</code>	Enables the DTM test APIs.

#### 4.2.1 CONFIG\_FLAGS

Currently only one config flag is supported, `SL_BT_CONFIG_FLAG_RTOS`, which needs to be set if the application uses RTOS.

#### 4.2.2 Mbedtls

The Mbedtls cryptography library used by the stack is configured using a configuration file that defines what algorithms are supported and if the implementation uses hardware acceleration or is done on software. The Mbedtls configuration file path is given using `#define MBEDTLS_CONFIG_FILE`. The default configuration file `mbedtls_config.h` should be used as a template if the configuration needs to be changed. Additionally, the project must contain `sl_bt_mbedtls_context.c`, which is provided as source in the SDK. It is used to by the stack to get Mbedtls context sizes, which depend on the Mbedtls configuration used.

#### 4.2.3 Multiprotocol Priority Configuration

When the Bluetooth stack is used with other protocols in a multiprotocol environment, it may become necessary to change the Bluetooth priority settings for RAIL to optimize certain use cases.

The application needs to allocate the configuration struct and provide it for the Bluetooth stack:

```
sl_bt_bluetooth_ll_priorities custom_priorities;
static const sl_bt_configuration_t config = {
    //
    .bluetooth.linklayer_priorities = &custom_priorities,
    //
};
```

The `sl_bt_bluetooth_ll_priorities` struct must be initialized to default state by the `SL_BT_BLUETOOTH_PRIORITIES_DEFAULT` constant.

The `sl_bt_bluetooth_ll_priorities` structure contain following fields:

- `scan_min`, `scan_max`, `scan step` - The priority range for scan operation.
- `adv_min`, `adv_max`, `adv step` - The priority range for advertisement operation.
- `conn_min` & `conn_max` - The priority range for connection packets.
- `init_min` & `init_max` - The priority range for connection initiation.
- `rail_mapping_offset` - The RAIL priority level where Bluetooth priorities are located.
- `rail_mapping_range` - The RAIL priority range where Bluetooth priorities are located.

For each priority range, 0 is the maximum priority, and 0xff is the minimum priority. Bluetooth priorities are different from RAIL priorities. That is, Bluetooth has its own space between 0 and 0xff where all Bluetooth priorities are located. To map Bluetooth priorities to RAIL priorities, the values in fields `rail_mapping_offset` and `rail_mapping_range` are used to form single-degree equation:

$$\text{RAIL\_priority} = (\text{BT\_priority} / 0xFF) * \text{rail\_mapping\_range} + \text{rail\_mapping\_offset}$$

#### 4.2.4 Sleep

Wireless Gecko's sleep mode EM2 (energy mode two) is automatically enabled in the `sl_power_manager_init()` function. Sleep modes are handled automatically by the stack in the case of blocking events, as described in section 5. [Bluetooth Stack Event Handling](#).

The sleep modes require that an accurate 32 kHz low-frequency clock (LFCLK) is present in the hardware. If an accurate sleep clock is not available for the Bluetooth stack and the application must support Bluetooth connections, then low power sleep modes cannot be entered. For applications where low power sleep modes are not needed, the LFXO or LFRCO can be left out.

#### Disabling Sleep at Runtime

If the application needs to disable sleep at runtime, it can be done by implementing `bool app_is_ok_to_sleep()` function. The function is called when the device wants to sleep. While EM2 is disabled (/blocked), the stack will switch between EM0 and EM1. For more information, refer to knowledge base article [Using Energy Modes with Bluetooth Stack](#).

#### 4.2.5 Bluetooth Stack Configuration

##### Buffer Memory

The Bluetooth stack uses memory for buffering API events and the data transmitted in Bluetooth connections, advertising, and scanning. This buffer memory is allocated from the heap by the Bluetooth stack when calling `sl_bt_init_stack()`. The size of buffer memory in bytes is defined by C-define `SL_BT_CONFIG_BUFFER_SIZE` in `sl_bluetooth_config.h`. The default value is an estimation for achieving adequate throughput and supporting multiple simultaneous connections. Consider increasing this value if the application needs higher data throughput over connections or uses advertising or scanning with long advertisement data.

Example of setting the buffer memory size:

```
static const sl_bt_configuration_t config = {
//
.bluetooth.max_buffer_memory = SL_BT_CONFIG_BUFFER_SIZE,
//
};
```

##### Number of Connections

The absolute maximum number of simultaneous Bluetooth connections is 8. The amount of memory that is allocated for connection management further limits the number of connections. The memory is allocated from the heap during initialization in `sl_bt_init_stack()`. C-define `SL_BT_CONFIG_MAX_CONNECTIONS` can be defined to set the number of connections. `SL_BT_CONFIG_MAX_CONNECTIONS` is passed to Bluetooth stack in the `.bluetooth.max_connections` field in the configuration struct.

Example of limiting the Bluetooth connections to one (1).

```
#define SL_BT_CONFIG_MAX_CONNECTIONS 1
```

For more information about connection RAM usage, refer to [7.3.2 Bluetooth Object Pools](#).

##### Advertisers

The maximum number of advertisement sets can be defined by this configuration option. These sets can be used to start multiple advertisers. This configuration option also configures the maximum number of periodic advertisements. Each advertisement context allocates ~60 bytes of RAM. The number of advertisers is defined with `SL_BT_CONFIG_USER_ADVERTISERS`.

```
.bluetooth.max_advertisers = SL_BT_CONFIG_USER_ADVERTISERS; //!< Maximum number of advertisers to support, if
0 defaults to 1
```

**Note:** Maximum connectable advertisements are limited by `MAX_CONNECTIONS`.

##### Periodic Advertisement Synchronization

The maximum number of supported periodic advertisement synchronizations needs to be configured. Each synchronization context allocates ~40 bytes of RAM.

```
.bluetooth.max_periodic_sync = 5; //!< Maximum number of periodic advertisement synchronizations to support.
Default is 0.
```

## 4.2.6 PA

On EFR32 SoC-based designs, the PAVDD (Power Amplifier voltage regulator VDD input) can be supplied from the output of the DC/DC or straight from a 3.3 V power supply.

The Bluetooth stack configuration defaults to using DC/DC as the PAVDD input. If PAVDD is being supplied from a 3.3 V power supply then the `.pa.input` field needs to be defined.

The Bluetooth stack automatically selects the high-power PA if available. The `pa_mode` configuration can be used to select the PA mode used by the Bluetooth stack. EFR32[B|M]G21 has 3 PAs so the `pa_mode` setting in the Bluetooth config struct can take 3 values. Other devices have 2 PAs.

```
.pa.config_enable = 1,          // PA Configuration is enabled
.pa.input = SL_BT_RADIO_PA_INPUT_VBAT, // PAVDD is supplied from an 3.3 V power supply
.pa.pa_mode=0                  // selects high power PA if available
```

## 4.2.7 Software Timers

Maximum available software timers can be configured. Each timer needs resources from the stack to be implemented. Increasing amount of soft timers may cause degraded performance in some use cases.

```
.max_timers = 4;
```

## 4.2.8 RF Path

### Gain

The application can define RF path gain values for RX and TX separately.

The Bluetooth stack takes TX RF path gain into account when adjusting transmitter power. Power radiated from the antenna then matches the application request. For example, if maximum power requested by the application is at +10 dBm and path loss is -1 dBm, then actual power at the pin is +11 dBm.

RX RF path gain is used to compensate the RSSI reports from the Bluetooth Stack.

```
.rf.tx_gain = -20; // RF TX path gain in unit of 0.1 dBm
.rf.rx_gain = -18; // RF RX path gain in unit of 0.1 dBm
```

### Output selection

On EFR32[B|M]G21 SoC-based designs, the RF output can be selected.

```
.rf.flags = SL_BT_RF_CONFIG_ANTENNA; // enabling output configuration
.rf.antenna = 0; // desired output,
```

For the correct value refer to the antenna path selection in the RAIL header file `rail_chip_specific.h`.

## 4.2.9 NVM3 Error Codes

The Bluetooth stack maps NVM3 error codes to the corresponding `sl_status` code if one exists. Other NVM3 error codes are mapped using base value `0x480 + NVM3 error value`. The NVM3 error values can be found from `platform/emdrv/nvm3/inc/nvm3.h`. For example `ECODE_NVM3_ERR_ALIGNMENT_INVALID` would be mapped as `0x481`.

## 5. Bluetooth Stack Event Handling

The Bluetooth stack for the Wireless Geckos is an event-driven architecture, where events are handled in the main while loop.

### 5.1 Blocking Event Listener

`sl_bt_wait_event()` is an implementation of a blocking wait function, which waits for events to emerge to the event queue and returns them to the event handler. This is the recommended mode of operation with the Bluetooth stack, because it manages the sleep most efficiently and automatically, while keeping the device and connections in sync.

- The `sl_bt_wait_event()` function processes the internal message queue until an event is received.
- If there are no pending events or messages to process, the device goes to EM1 or EM2 sleep mode.
- The function copies the received event data to an `sl_bt_msg_t` structure.

The code snippet below shows the simple main while loop using `sl_bt_wait_event()`, which sets up advertising after boot.

```
/* Main loop */ while (1) {
sl_bt_msg_t evt;

/* Wait (blocking) for a Bluetooth stack event. */
SL_STATUS status = sl_bt_wait_event(&evt);

/* Run application and event handler. */
switch (SL_BT_MSG_ID(evt.header))
{
/* This boot event is generated when the system is turned on or reset. */
case sl_bt_evt_system_boot_id:

/* Initialize iBeacon ADV data */
bcnSetupAdvBeaconing();
break;

/* Ignore other events */
default:
break;
}
```

## 5.2 Non-Blocking Event Listener

This mode of operation requires more manual adjustment, for example sleep management needs to be done by the application. In some use cases non-blocking operation is required. This is the default way in which event processing is done in example applications.

- The `sl_bt_pop_event()` function processes the internal message queue until an event is received or all of the messages are processed.
- The function copies the received event data to an `sl_bt_msg_t` structure, or returns `SL_STATUS_NOT_FOUND` if there are no events in the queue.

The application can override a dummy weak implementation of `sl_bt_on_event()` to implement the event handler. It is automatically called from the applications main loop. Below is an example from the soc-empty application.

```
void sl_bt_on_event(sl_bt_msg_t* evt)
{
    sl_status_t sc;

    // Handle stack events
    switch (SL_BT_MSG_ID(evt->header)) {
        case sl_bt_evt_system_boot_id:

            // Create an advertising set.
            sc = sl_bt_advertiser_create_set(&advertising_set_handle);
            app_assert(sc == SL_STATUS_OK,
                      "[E: 0x%04x] Failed to create advertising set\n",
                      (int)sc);

            // Start general advertising and enable connections.
            sc = sl_bt_advertiser_start(
                advertising_set_handle,          // advertising set handle
                advertiser_general_discoverable,  // discoverable mode
                advertiser_connectable_scannable); // connectable mode
            app_assert(sc == SL_STATUS_OK,
                      "[E: 0x%04x] Failed to start advertising\n",
                      (int)sc);

            break;

        default:
            break;
    }
}
```

### 5.2.1 Sleep and Non-Blocking Event Listener

When an application uses the non-blocking `sl_bt_pop_event()` function to create an event handler, the sleep implementation differs as well. The application can use `app_is_ok_to_sleep()` to tell the power manager if the application allows the device to sleep or not.

### 5.2.2 Notification for Updating Event Listener

In some cases, there may be a need for running the Bluetooth event loop inside another event loop in the application. The Bluetooth stack has a callback mechanism for notifying the application about the demand for updating the Bluetooth stack event listener. This is enabled by defining a callback function in the Bluetooth configuration struct.

**Note:** This `stack_schedule_callback` is called from the interrupt context. It is important NOT to call `sl_bt_pop_event` or `sl_bt_wait_event` from this context. The application must set a flag or use another mechanism for enabling the application main loop to update the Bluetooth stack.

```
static const sl_bt_configuration_t config = {
    //
    .stack_schedule_callback = bluetooth_update
    //
};

void bluetooth_update()
{
    //set notification for application
}
```

### 5.3 Event Listener with Micrium OS

The application uses a different procedure to receive an event with Micrium OS. Instead of calling the function to receive events, the application needs to pend for a Micrium OS flag. Events can be only received from a single task.

Micrium OS flags in `bluetooth_event_flags` are used to notify different tasks about the state of the Bluetooth stack. The application only uses `BLUETOOTH_EVENT_FLAG_EVT_WAITING` and `BLUETOOTH_EVENT_FLAG_EVT_HANDLED`.

The application event handler needs to pend for `BLUETOOTH_EVENT_FLAG_EVT_WAITING`.

```
OSFlagPend(&bluetooth_event_flags, (OS_FLAGS)BLUETOOTH_EVENT_FLAG_EVT_WAITING
0, OS_OPT_PEND_BLOCKING + OS_OPT_PEND_FLAG_SET_ANY +
OS_OPT_PEND_FLAG_CONSUME, NULL, &os_err);
```

The incoming event is then available in `bluetooth_evt`.

```
switch (SL_BT_MSG_ID(bluetooth_evt->header)) {
    ...
}
```

After the event is handled, it needs to be freed to allow the next event to be received. This is done by notifying the Bluetooth task by posting the flag `BLUETOOTH_EVENT_FLAG_EVT_HANDLED`.

```
OSFlagPost(&bluetooth_event_flags, (OS_FLAGS)BLUETOOTH_EVENT_FLAG_EVT_HANDLED, OS_OPT_POST_FLAG_SET, &os_err);
```

**Note:** When the application is pending, sleep and power management are automatically handled by Micrium OS rather than by the application.

#### 5.3.1 Commands from Multiple Tasks

It is possible to send Bluetooth commands from multiple Micrium OS tasks. It requires that each task acquires exclusivity before sending the commands and releases it afterward.

The Bluetooth stack provides two functions for convenience. `BluetoothPend` acquires the Micrium OS mutex and `BluetoothPost` releases the mutex.

The following code block acquires the mutex for Bluetooth before the Bluetooth command and releases it afterward.

```
BluetoothPend(&err); //acquire mutex for Bluetooth stack
gecko_cmd_gatt_server_send_characteristic_notification(0xff, gattdb_temp_measurement, 5, temp_buffer);
BluetoothPost(&err); //release mutex
```

## 6. Interrupts

Interrupts create events in their respective interrupt handlers, be it radio interrupts or interrupts from IO pins. The events are later processed in the main event loop from the message queue. The application should always minimize the processing time within an interrupt handler, and leave the processing for event callbacks or to the main loop.

In general, the interrupt scheme is according to any event-based programming architecture, but a few unique and important exceptions apply to the Bluetooth stack:

- BGAPI commands cannot be called from interrupt context.
- Only the `sl_bt_external_signal()` function can be called from interrupt context.

### 6.1 External Event

An external event is used to capture all peripheral interrupts as an external signal to be passed to the main event loop and to be processed within that loop. The external event interrupt can come from any of the peripheral interrupt sources, for example IOs, comparators, or ADCs, to name a few. The signal bit array is used for notifying the event handler of what external interrupts have been issued.

- The main purpose of the external signal is to trigger an event from the interrupt context to the main event loop.
- The BGAPI event `sl_bt_evt_system_external_signal` can be generated by calling the `void sl_bt_external_signal(uint32 signals)` function.
- The function `sl_bt_external_signal` can be called from the interrupt context.
- The `signals` parameter of the `sl_bt_external_signal` function is passed to the `sl_bt_evt_system_external_signal` event.

```
/**
 * Main
 */
void main()
{
    ...

    //Event loop
    while(1)
    {
        ...

        //External signal indication (comes from the interrupt handler)
        case sl_bt_evt_system_external_signal_id:
            // Handle GPIO IRQ and do something
            // External signal command's parameter can be accessed using
            // event->data.evt_system_external_signal.extsignals
            break;
        ...
    }
}

/**
 * Handle GPIO interrupts and trigger system_external_signal event
 */
void GPIO_ODD_IRQHandler()
{
    static bool radioHalted = false;

    uint32_t flags = GPIO_IntGet();
    GPIO_IntClear(flags);

    //Send gecko_evt_system_external_signal_id event to the main loop
    sl_bt_external_signal(...);
}
}
```

## 6.2 Priorities

It is highly recommended that the radio should have the highest priority interrupts. This is the default configuration, and other interrupts are handled with lower priority. Default interrupt priorities for radio is 1, for Link Layer the priority is 2, USART interrupts are 3, and other interrupts have default priority of 4.

If the application needs to disable interrupts, it is recommended that the `BASEPRI` register is used instead of the `PRIMASK` register. The `BASEPRI` register disables with interrupt priority, whereas `PRIMASK` disables all interrupts. EMLIB Core can be configured to use the `BASEPRI` register, and it can then be used with the `CORE_ENTER_ATOMIC()` and `CORE_EXIT_ATOMIC()` macros.

Without RTOS, Link Layer uses PendSV for achieving priority over the application software. With RTOS the Link Layer will not use PendSV, but Link Layer task will have higher priority over application task. RTOS scheduler will then give priority to Link Layer task over application task.

The following table describes the three different components within the Bluetooth stack that run in different operating contexts, and their maximum time to disable interrupts in order for each component to assure connections.

Component	Description	Timing Accuracy	Operating Context	Maximum IRQ Disable	If Timing Requirements are Ignored
Radio	Time-critical low level TX/RX radio control	Microseconds	Radio IRQ	< ~10 $\mu$ s	Packets are not transmitted or received, which will eventually cause supervision timeout and Bluetooth link loss.
Link layer	Time-critical connection management procedures and encryption	Milliseconds	PendSV IRQ*	< ~20 ms	If the link control procedure is not handled in time, Bluetooth link loss may happen. Slave-side channel map update and connection update timings are controlled by master.
Host Stack	Bluetooth Host Stack, Security Manager, GATT	Seconds	Application	< 30 s	SMP and GATT have a 30 s timeout and if operations are not handled within that timeout Bluetooth link loss will occur.

\*PendSV interrupt is only used without RTOS

## 7. Wireless Gecko Resources

The Bluetooth stack uses some of the Wireless Gecko's resources, which are not available to the application. The following table lists the resources and describes their use by the stack. The first four resources (in red) are always used by the Bluetooth stack.

Category	Resource	Used in software	Notes
PRS	<b>PRS7</b>	PROTIMER RTC synchroni- zation	PRS7 always used by the Bluetooth stack.
Timers	<b>RTCC</b>	EM2 timings	The sleep timer uses RTCC in the default configuration.  In EFR32[B M]G13 and EFR32[B M]G2x, RTCC can be used by applica- tions if the sleep timer is configured to use another resource. See <a href="#">platform sleep timer documentation</a>
	<b>PROTIMER</b>	Bluetooth	The application does not have access to PROTIMER.
Radio	<b>RADIO</b>	Bluetooth	Always used and all radio registers are reserved for the Bluetooth stack.
GPIO	NCP	Host communication.	2 to 6 x I/O pins can be allocated for the NCP usage depending on used features (UART, RTS/CTS, wake-up and host wake-up).  Optional to use, and valid only for NCP use case.
	PTI	Packet trace	2 to N x I/O pins.  Optional to use.
	TX enable	TX activity indication	1 x I/O pin.  Optional to use.
	RX enable	RX activity indication	1 x I/O pin.  Optional to use.
	COEX	Wi-Fi coexistence	4 x I/O pin.  Optional to use.
CRC	GPCRC	PS Store	Can be used in application, but application should always reconfigure GPCRC before use, and GPCRC clock must not be disabled in CMU.
Flash	MSC	PS Store	Can be used by the application.
CRYPTO	CRYPTO	Bluetooth link encryption	The CRYPTO peripheral can only be accessed through the mbedTLS crypto library, not through any other means. The library should be able to do the scheduling between the stack and application access.

## 7.1 Flash

The application and Bluetooth stack are executed from the flash memory. The flash can be split into blocks for the bootloader, the Bluetooth AppLoader, application + Bluetooth stack, and non-volatile memory, as shown in the following figure.

- The bootloader is essential to enable Bluetooth stack and application upgradeability. The bootloader has been designed to be future-proof for bootloader improvements and feature additions. On devices with separate bootloader flash the bootloader is located there.
- The Bluetooth AppLoader provides OTA upgradability for the application. This is an optional feature, but using it requires that the bootloader is also used.
- PS Store and NVM3 are a non-volatile data stores (NVM), where both the Bluetooth stack and the application can store permanent data, such as Bluetooth bonding keys, application configuration data, hardware configurations, and so on. These cannot be used simultaneously. PS Store is only supported on Series 1 devices.
- The application is located between the Bluetooth AppLoader and NVM. The Bluetooth stack is a library that is linked with the application. The Bluetooth stack includes the actual Bluetooth firmware, including link layer, GAP, SM, ATT, and GATT layers.
- Manufacturing tokens storage is used for storing manufacturing tokens. On EFR32[B|M]G2x devices it is located at end of main flash.

**Figure 7.1. Flash Usage With and Without Separate Bootloader Flash**

The following table shows the flash usage for each block. The estimates can vary between use cases, configurations, application resources, or SDK version.

	Compiler	EFR32				
		[B M]G1	[B M]G12	[B M]G13	[B M]G21	[B M]G22
Bootloader		16	16	16	16	24
Bluetooth AppLoader		40	44	46	48	56
soc-empty*	GCC	142	152	154	150	162
	IAR	141	151	153	150	162
PS Store		4	4	4		
NVM3 <sup>+</sup>		6	6	6	24	24
Manufacturing tokens					8	8

\**soc-empty* is an example applications provided in the Bluetooth SDK. It is compiled with high size optimizations. GCC uses the `-Os` flag, and IAR the `-OHz` flag.

<sup>+</sup>NVM3 is an alternative to PS Store. They cannot be used simultaneously. NVM3 requires a minimum of 3 flash pages, and that is the default configuration in the Bluetooth sample applications in the SDK. Please refer to *AN1135: Using Third Generation Non-Volatile Memory (NVM3) Data Storage* for further information about NVM3.

### 7.1.1 Optimizing Flash Usage

#### Dead code elimination

Bluetooth stack libraries are designed to benefit from the linker's dead code elimination optimization. With this optimization all unused code will be removed from application.

To fully utilize this optimization feature, it is important not to call any function that is not needed for application. These include all initialization functions for the Bluetooth stack.

#### Selective Initialization of Bluetooth Stack Components

Each required stack component must be individually initialized. For more information, see section 4.2 [Bluetooth Configuration with sl\\_bt\\_init\\_stack\(\)](#).

## 7.2 Linking

The Bluetooth stack is delivered as a set of library files. The application links the Bluetooth stack libraries with the rest of application. The linker will then create an ELF-file, which contains the application code and data ready to be loaded into flash.

For generating OTA DFU files, the application's code and data must be linked into their own section in the ELF-file. This is automatically done with the linker files provided with the Gecko Platform.

**Figure 7.2. Sections Defined in the Linker File and Their Placement**

Depending on the device used, the bootloader is placed on separate flash memory or, if no separate bootloader flash exists, the linker file reserves some memory from main flash for the bootloader. Bluetooth AppLoader is placed at the beginning of main flash and the application with all libraries start from the next free flash page.

For more information on the OTA updates and how to enable them, please refer to *UG266: Silicon Labs Gecko Bootloader User's Guide* and *AN1086: Using the Gecko Bootloader with Silicon Labs Bluetooth Applications*.

## 7.3 RAM

The Bluetooth stack reserves part of the RAM from the Wireless Gecko and leaves the unused RAM for the application.

RAM consumption of the Bluetooth functionality is divided into:

- Bluetooth stack
- Bluetooth object pools
- Bluetooth buffer memory
- Bluetooth GATT database
- C STACK
- C HEAP

The following table shows the RAM allocations that are done statically at link time.

Component	Static allocation at link time	Configurable by
Bluetooth stack	6 kB	
Bluetooth GATT database	Application-dependent (20 to 200 bytes)	
Call stack	2 kB	SL_STACK_SIZE
Heap memory	8630 bytes	SL_HEAP_SIZE

The following table shows the RAM allocations that are done dynamically from the heap at run time.

Component	Static allocation at link time	Configurable by
Bluetooth stack	2 kB	
Bluetooth connection objects	1600 bytes = 400 bytes * 4	SL_BT_CONFIG_MAX_CONNECTIONS
Bluetooth advertiser objects	160 bytes = 160 bytes * 1	SL_BT_CONFIG_USER_ADVERTISERS
Bluetooth periodic advertising synchronization objects	0 bytes = 168 bytes * 0	SL_BT_CONFIG_MAX_PERIODIC_ADVERTISING_SYNC
Bluetooth software timers	160 bytes = 40 bytes * 4	SL_BT_CONFIG_MAX_SOFTWARE_TIMERS
Bluetooth buffer memory	3150 bytes	SL_BT_CONFIG_BUFFER_SIZE

### 7.3.1 Bluetooth Stack

The Bluetooth stack allocates around 6 kB of static RAM and 2 kB of heap for its internal use. It includes Bluetooth stack software with low-level radio drivers and the application programming interface.

### 7.3.2 Bluetooth Object Pools

The Bluetooth stack uses memory to store the necessary context for objects such as connections, advertisers, and periodic advertisement synchronizations. The number of these objects depends on the configuration. The table in section [7.3 RAM](#) summarizes the memory usage in the default configuration and shows which configuration items affect the number of objects allocated.

### 7.3.3 Bluetooth Buffer Memory

The Bluetooth stack uses memory for buffering API events and the data transmitted in Bluetooth connections, advertising, and scanning. This buffer memory is allocated from the heap by the Bluetooth stack when calling `sl_bt_init_stack()`. The size of buffer memory in bytes is defined by the C-define `SL_BT_CONFIG_BUFFER_SIZE` in `sl_bluetooth_config.h`. The default value is an estimation for achieving adequate throughput and supporting multiple simultaneous connections. Consider increasing this value if the application needs higher data throughput over connections or uses advertising or scanning with long advertisement data.

### 7.3.4 Bluetooth GATT Database

The Bluetooth GATT database uses statistically-allocated RAM. The amount of RAM used depends on the user-defined GATT database and cannot be generalized. All characteristics with write enabled use as much RAM as their length defined. Plus, every attribute in GATT needs a few bytes of RAM for maintaining the Attribute permissions. Typical RAM usage is approximately 20 to 200 bytes.

### 7.3.5 Call Stack

The Bluetooth stack requires at least a 1.5 kB call stack to be reserved from RAM. Application developers must allocate RAM for the application call stack on top of the 1.5 kB required by the stack. The size of the call stack is configured by `SL_STACK_SIZE` in `sl_memory_config.h`.

### 7.3.6 Heap memory

The Bluetooth stack uses the heap to allocate storage for object contexts and the stack internal state as summarized in the table in section [7.3 RAM](#). In addition to these allocations, the Bluetooth stack requires heap memory for asymmetric encryption operations using the elliptic curve algorithms during Bluetooth pairing.

The C-define `SL_HEAP_SIZE` in `sl_memory_config.h` defines the minimum heap size that is allocated from the physical RAM at link time. The actual heap size at runtime can end up being larger than the minimum to make use of any available physical memory that would otherwise have remained unallocated.

The default minimum heap size is 8630 bytes, which is sufficient for running the Bluetooth examples with the default Bluetooth configuration. The application should configure the minimum heap size to take into account the Bluetooth configuration used and any extra heap that the application may require.

## 8. Application ELF-file

ELF (Executable and Linkable Format) is a standard file format for executable files. This chapter describes the sections in the ELF file related to the application and the Bluetooth stack.

Some linkers provide output describing the consumed flash, but what it contains is not obvious. A Bluetooth project might contain a bootloader and the Bluetooth AppLoader, and the device might have separate flash for the bootloader. The ELF-file provides exact information about RAM and flash usage.

Simplicity Studio provides the GCC toolchain, which contains command line tool *objdump*. This tool can be used to get section information from the ELF-file.

*objdump* requires input ELF-file. If the parameter *-h* is used, *objdump* dumps the section header information.

### IAR

Calling *objdump* from the command line for an example application:

```
arm-none-eabi-objdump -h ewarm-iar/exe/soc_empty.out
```

*objdump* then gives the following output:

```
Sections:
Idx Name          Size      VMA           LMA           File off  Algn

```

*.text\_apploader* contains the Bluetooth AppLoader.

*.text\_signature* is the space reserved for the AppLoader signature.

*.text* contains the application code and read-only data. Size of the application in this example is 0x289f0 in hexadecimal, and 166384 bytes in decimal.

*.stack* is a RAM section for the call stack.

*.data* is the RAM section for initialized variables.

*.bss* is the RAM section for uninitialized variables..

*.heap* is the RAM section for heap.

Refer to IAR documentation for description of the remaining sections.

### GCC

Calling *objdump* from the command line for an example application:

```
arm-none-eabi-objdump -h build/debug/soc_empty.out
```

*objdump* then gives the following output:

```
Sections:

```

`.text_apploader` contains the Bluetooth AppLoader.

`.text_signature` is the space reserved for the AppLoader signature.

`.text` contains the application code and read-only data. The size of the application in this example is 0x289dc in hexa- decimal and 166364 bytes in decimal.

`.ARM.exidx` is used for debugging.

`.stack` is a RAM section for the call stack

`.data` is the RAM section for initialized variables.

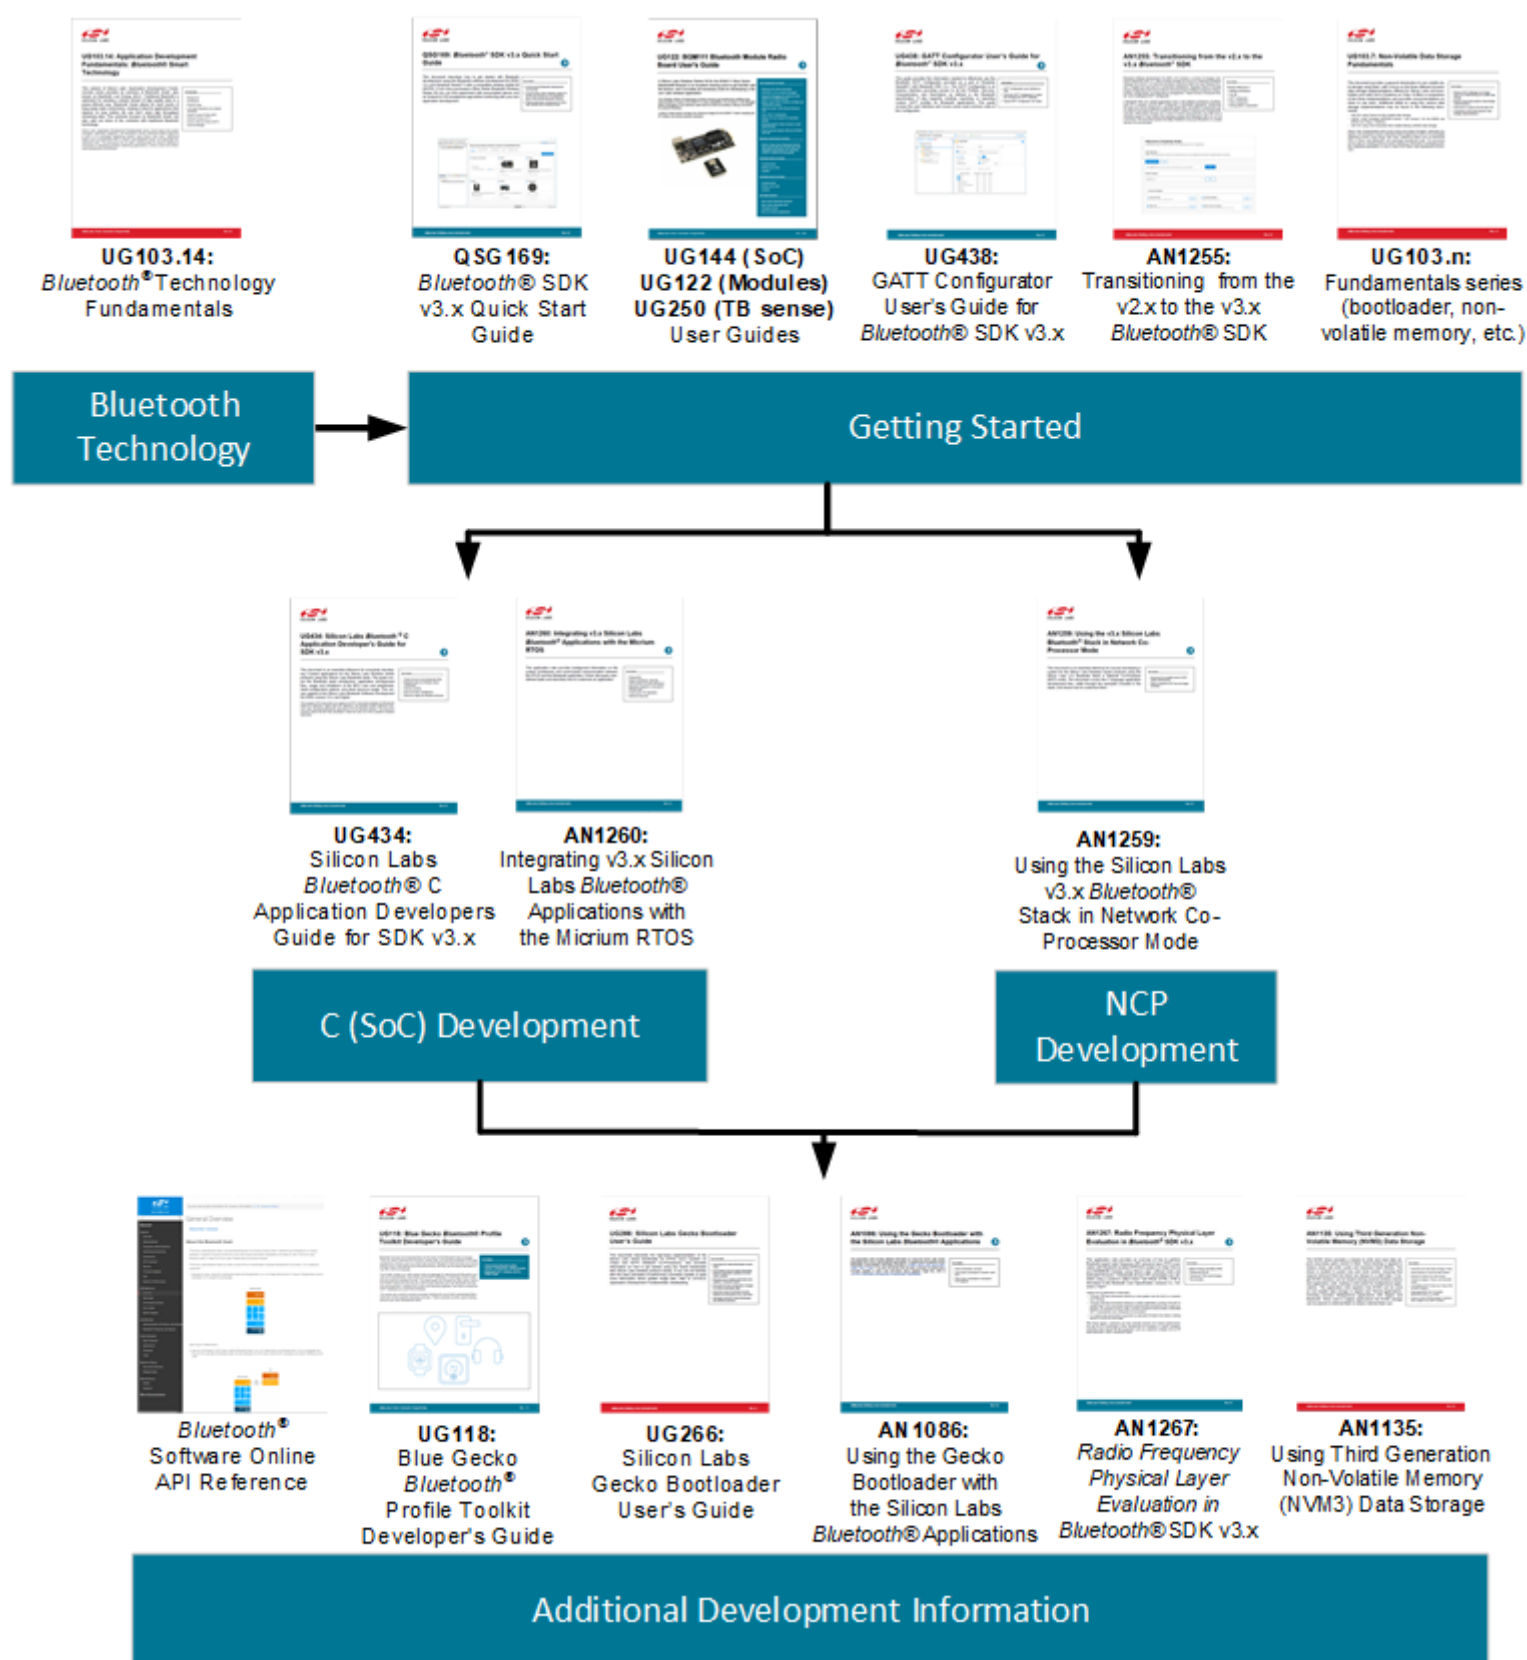

`.bss` is the RAM section for uninitialized variables.

`.heap` is the RAM section for heap.

Refer to GCC documentation for a description of the remaining sections.

## 9. Documentation
